Processes of this kind are basic to many gas phase chemical reactions and also to phenomena such as the vibrational relaxation that has been suggested as a mechanism for the large absorption of high-frequency sound in gases. Numerous quantum mechanical calculations of this kind of process have been made and the correct order of magnitude for the cross section has been obtained. The problem of measuring cross sections for this kind of process experimentally is a very difficult one because the energy of translation is low, so that no detailed numerical data such as angular distributions can be expected. From a theoretical standpoint there are serious difficulties connected with the form of the intermolecular potential, and also with the mathematical treatment of the translational motion. On account of the complexity of the problem, which arises from the large number of electrons and nuclei involved, it has not been possible to give convincing quantitative calculations of the intermolecular (van der Waals) potential for any but the very simplest systems. The quantitative knowledge that is available on the van der Waals potential of most molecules has been derived from a knowledge of macroscopic properties of the gas, such as the viscosity and the second virial coefficient, by means of various statistical mechanical models.
